

Are categorical biases a result of verbal coding?

Categorical biases are present when recalling orientations and locations: cardinal stimuli are reported more accurately.<sup>1,2,3,4</sup>

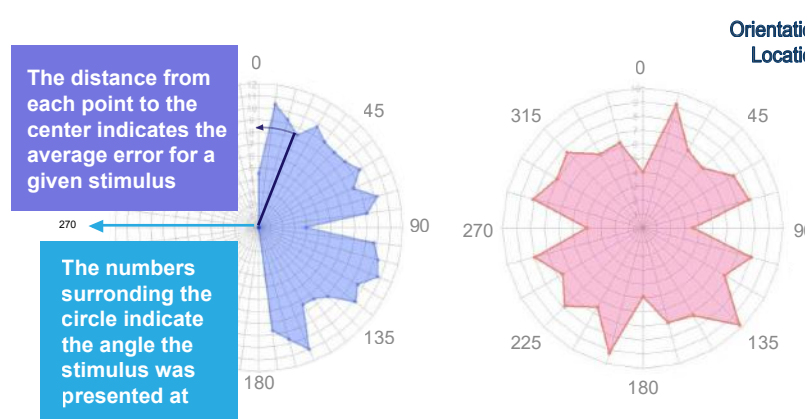

Subjects frequently report using verbal labels in memory tasks.

The usage of verbal labels provides a benefit when recalling visual stimuli:  
We believe one item can have multiple neural representations, different in nature.<sup>6</sup>

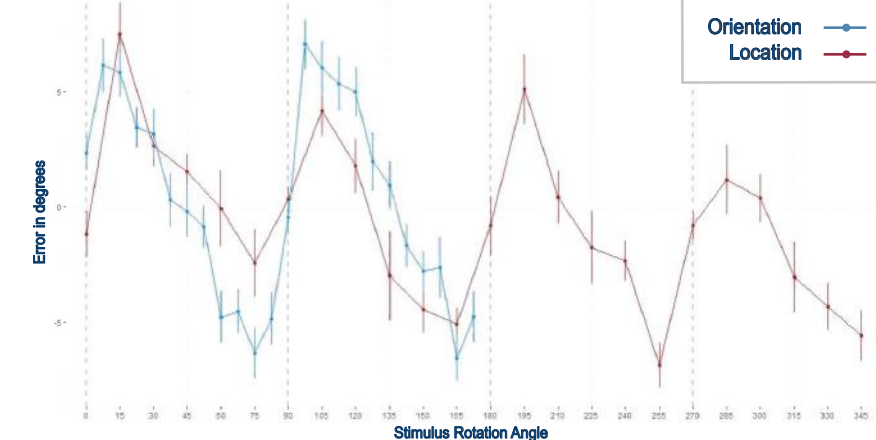

Does recall error differ for cardinal and non-cardinal stimuli?

Absolute Error for Orientation and Location

Increased accuracy for cardinal stimuli

Relative Error for Orientation and Location

Direction of error away from cardinals

Error distribution similar in both stimulus types

We found behavioural evidence that verbal coding drives categorical biases during working memory.

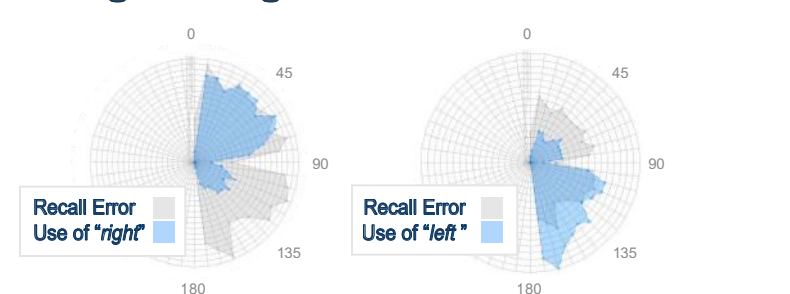

A neuroimaging study is needed to investigate detailed and semantic representations, and the interaction between the two.

Are semantic strategies involved in the recall of visual stimuli?

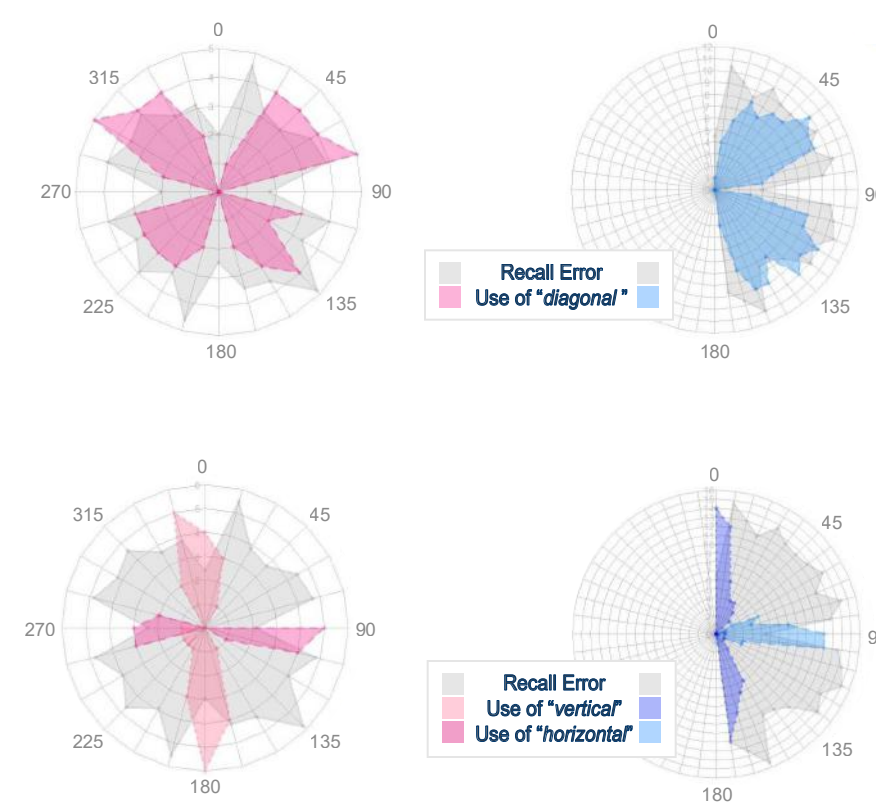

Word Usage for Orientations in Upper Right Quadrant

Usage of "right" and "left" for Orientations

Word Usage in Relation to Recall Error

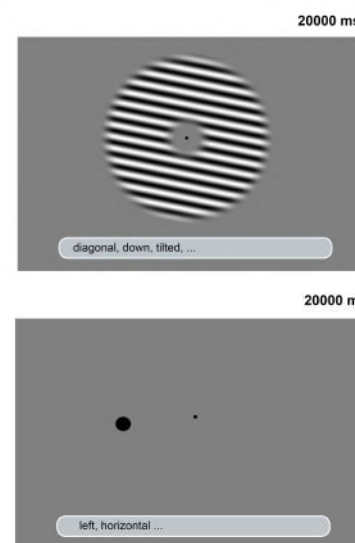

How did we study this?

Memory Task

Stimulus Naming

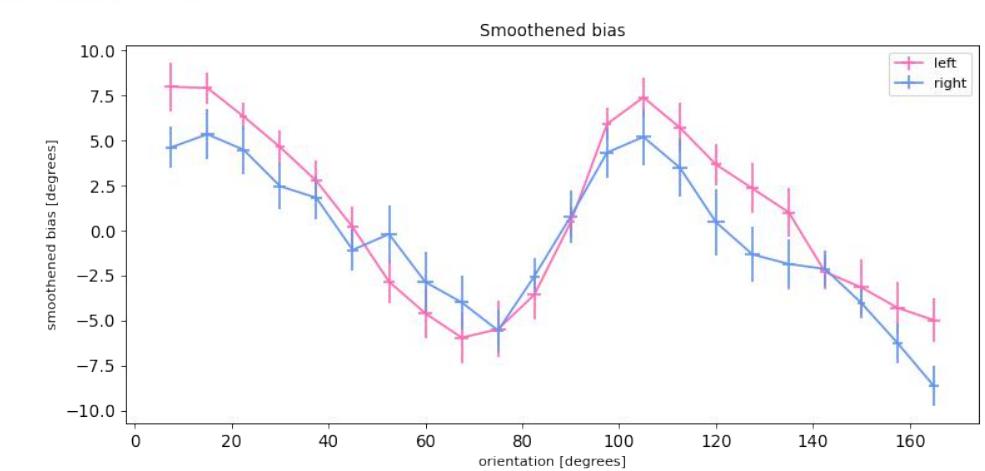

If verbal coding drives categorical biases, can verbal distractors impair recall accuracy?

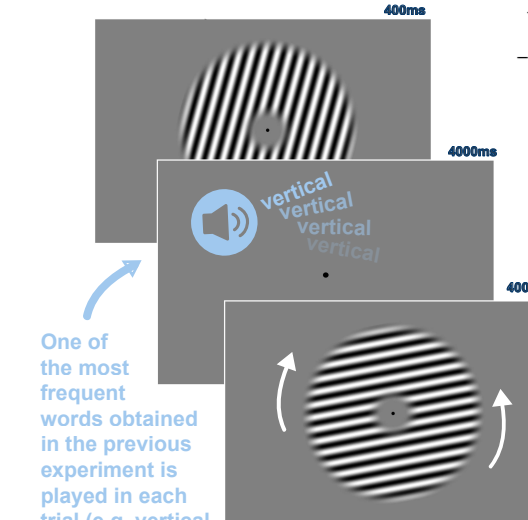

WORK IN PROGRESS

Recall Error After Presentation of the Distractors "left" and "right"

Memory Task with Semantic Distractor
